# **WEEK 13**

**STATISTICAL INFERENCE - HYPOTHESIS TESTING**

**INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN**

**INFERENCE ON THE VARIANCE OF THE NORMAL POPULATION**

# HYPOTHESIS TESTING AND STATISTICAL INFERENCE FOR A SINGLE SAMPLE

## General Procedure for Hypothesis Tests

Use of the following sequence of steps in applying hypothesis-testing methodology is recommended.

1. From the problem context, identify the parameter of interest.
2. State the null hypothesis,  $H_0$ .
3. Specify an appropriate alternative hypothesis,  $H_1$ .
4. Choose a significance level  $\alpha$ .
5. Determine an appropriate test statistic.
6. State the rejection region for the statistic.
7. Compute any necessary sample quantities, substitute these into the equation for the test statistic, and compute that value.
8. Decide whether or not  $H_0$  should be rejected and report that in the problem context.

# HYPOTHESIS TESTING AND STATISTICAL INFERENCE FOR A SINGLE SAMPLE

- Be careful that level of significance as being equal to  $\alpha$  for one sided hypothesis
- And  $\alpha/2$  for two sided hypothesis

**Figure 9-6** The distribution of  $Z_0$  when  $H_0: \mu = \mu_0$  is true, with critical region for (a) the two-sided alternative  $H_1: \mu \neq \mu_0$ , (b) the one-sided alternative  $H_1: \mu > \mu_0$ , and (c) the one-sided alternative  $H_1: \mu < \mu_0$ .

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Exercise 1

Aircrew escape systems are powered by a solid propellant. The burning rate of this propellant is an important product characteristic. Specifications require that the mean burning rate must be 50 centimeters per second. We know that the standard deviation of burning rate is  $\sigma = 2$  centimeters per second. The experimenter decides to specify a type I error probability or significance level of  $\alpha = 0.05$  and selects a random sample of  $n = 25$  and obtains a sample average burning rate of  $\bar{x} = 51.3$  centimeters per second. What conclusions should be drawn?

A normal distribution curve is shown. The horizontal axis is labeled with  $z$  and has a tick mark at  $-1$ . The area under the curve to the left of  $z = -1$  is shaded in teal.

[illegible]

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Exercise 1

We may solve this problem by following the eight-step procedure outlined in Section 9-1.4. This results in

1. The parameter of interest is  $\mu$ , the mean burning rate.
2.  $H_0: \mu = 50$  centimeters per second
3.  $H_1: \mu \neq 50$  centimeters per second
4.  $\alpha = 0.05$
5. The test statistic is

$$z_0 = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}}$$

6. Reject  $H_0$  if  $z_0 > 1.96$  or if  $z_0 < -1.96$ . Note that this results from step 4, where we specified  $\alpha = 0.05$ , and so the boundaries of the critical region are at  $z_{0.025} = 1.96$  and  $-z_{0.025} = -1.96$ .
7. Computations: Since  $\bar{x} = 51.3$  and  $\sigma = 2$ ,

$$z_0 = \frac{51.3 - 50}{2/\sqrt{25}} = 3.25$$

8. Conclusion: Since  $z_0 = 3.25 > 1.96$ , we reject  $H_0: \mu = 50$  at the 0.05 level of significance. Stated more completely, we conclude that the mean burning rate differs from 50 centimeters per second, based on a sample of 25 measurements. In fact, there is strong evidence that the mean burning rate exceeds 50 centimeters per second.

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Extra Exercise 1

Suppose a production line operates with a mean filling weight of 16 ounces per contained. Since over or under filling can be dangerous, a quality control inspector samples 30 items to determine whether or not the filling weight has to be adjusted. The sample revealed a mean of 16.32 ounces. From the past data, the standard deviation is known to be 0.8 ounces. Using a 0.1 level of significance, can it be concluded that the process is out of control (not equal to 16 ounces)

A normal distribution curve is shown with a horizontal axis. A vertical line is drawn at a point labeled  $z$  on the axis. The area under the curve to the left of this line is shaded in teal.

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Extra Exercise 1

Suppose a production line operates with a mean filling weight of 16 ounces per container. Since over-or-under filling can be dangerous, a quality control inspector samples 30 items to determine whether or not the filling weight has to be adjusted. The sample revealed a mean of 16.32 ounces. From past data, the standard deviation is known to be 0.8 ounces. Using a 0.10 level of significance, can it be concluded that the process is out of control(not equal to 16 ounces)?

From Z table for shaded region is equal to 0.05

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Extra Exercise 1

Suppose a production line operates with a mean filling weight of 16 ounces per container. Since over-or-under filling can be dangerous, a quality control inspector samples 30 items to determine whether or not the filling weight has to be adjusted. The sample revealed a mean of 16.32 ounces. From past data, the standard deviation is known to be 0.8 ounces. Using a 0.10 level of significance, can it be concluded that the process is out of control(not equal to 16 ounces)?

$$\begin{aligned} H_0: & \mu = 16 \\ H_a: & \mu \neq 16 \\ Z = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} = \frac{16.32 - 16}{\frac{0.8}{\sqrt{30}}} = 2.19 \end{aligned}$$

Reject  $H_0$  if  $Z < -1.65$  OR  $Z > 1.65$

Reject  $H_0$

There is sufficient evidence to conclude the process is out of control,  $\alpha = 0.10$ .

From Z table for shaded region is equal to 0.05

# STATISTICAL INFERENCE ON THE MEAN OF A NORMAL DISTRIBUTION, VARIANCE KNOWN

## Extra Exercise 2

Suppose we would like to determine if the typical amount spent per customer for dinner at a new restaurant in town is \$20.00. A sample of 49 customers over a three week period was randomly selected and the average amount spent was \$22.60. Assume that the standard deviation is known to be \$2.5. Using a 0.02 level of significance, would we conclude the typical amount spent per customer is more than \$20.00

## Extra Exercise 2

2. Suppose we would like to determine if the typical amount spent per customer for dinner at a new restaurant in town is **more than** \$20.00. A sample of 49 customers over a three-week period was randomly selected and the average amount spent was \$22.60. Assume that the standard deviation is known to be \$2.50. Using a 0.02 level of significance, would we conclude the typical amount spent per customer is more than \$20.00?

$$\begin{aligned} 1. \quad & H_0: \mu = 20 \\ & H_a: \mu > 20 \end{aligned}$$

$$Z = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} = \frac{22.60 - 20}{\frac{2.50}{\sqrt{49}}} = 7.28$$

Reject  $H_0$  if  $Z > 2.06$

Reject  $H_0$

There is sufficient evidence to conclude the typical amount spent per customer is more than \$20.00,  $\alpha = 0.02$ .

From Z table where shaded region is equal to 0.05 at right hand side of the distribution

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

We now consider the case of **hypothesis testing** on the mean of a population with **unknown variance  $\sigma^2$** .

We will use the **test statistic**

$$H_0: \mu = \mu_0$$

$$H_1: \mu \neq \mu_0$$

$$T_0 = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$$

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

Test statistic:  $T_0 = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$

Alternative hypothesis	Rejection criteria
$H_1: \mu \neq \mu_0$	$t_0 > t_{\alpha/2, n-1}$ or $t_0 < -t_{\alpha/2, n-1}$
$H_1: \mu > \mu_0$	$t_0 > t_{\alpha, n-1}$
$H_1: \mu < \mu_0$	$t_0 < -t_{\alpha, n-1}$

Figure 9-8 shows the location of the critical region for these situations.

**Figure 9-8** The reference distribution for  $H_0: \mu = \mu_0$  with critical region for (a)  $H_1: \mu \neq \mu_0$ , (b)  $H_1: \mu > \mu_0$ , and (c)  $H_1: \mu < \mu_0$ .

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

## Example 8.8

An article in the journal describes the results of tensile adhesion tests on 22 U-700 alloy specimens. The load at the specimen failure is as follows in Mpa. Do the data suggest that the mean load at failure exceeds 10. Mpa. Assume that the load at failure has a normal distribution and use  $\alpha$  as 0.05

19.8	18.5	17.6	16.7	15.8
15.4	14.1	13.6	11.9	11.4
11.4	8.8	7.5	15.4	15.4
19.5	14.9	12.7	11.9	11.4
10.1	7.9			

(The sample mean is 13.71 and the sample standard deviation is 3.55.)

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

$\infty$	1.282	1.645	1.960	2.326	2.576	3.090	3.291

## Example 8.8

The solution using the eight-step procedure for hypothesis testing is as follows:

1. The parameter of interest is the mean load at failure,  $\mu$ .
2.  $H_0: \mu = 10$
3.  $H_1: \mu > 10$ . We want to reject  $H_0$  if the mean load at failure exceeds 10 MPa.
4.  $\alpha = 0.05$
5. The test statistic is

$$t_0 = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

6. Reject  $H_0$  if  $t_0 > t_{0.05,21} = 1.721$ . From T table
7. Computations: Since  $\bar{x} = 13.71$ ,  $s = 3.55$ ,  $\mu_0 = 10$ , and  $n = 22$ , we have

$$t_0 = \frac{13.71 - 10}{3.55/\sqrt{22}} = 4.90$$

8. Conclusions: Since  $t_0 = 4.90 > 1.721$ , we reject  $H_0$  and conclude at the 0.05 level of significance that the mean load at failure exceeds 10 MPa.

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

## Extra Exercise 1

The increased availability of light materials with high strength has revolutionized the design and manufacture of golf clubs, particularly drivers. Clubs with hollow heads and very thin faces can result in much longer tee shots, especially for players of modest skills. This is due partly to the “spring-like effect” that the thin face imparts to the ball. Firing a golf ball at the head of the club and measuring the ratio of the outgoing velocity of the ball to the incoming velocity can quantify this spring-like effect. The ratio of velocities is called the coefficient of restitution of the club. An experiment was performed in which 15 drivers produced by a particular club maker were selected at random and their coefficients of restitution measured. In the experiment the golf balls were fired from an air cannon so that the incoming velocity and spin rate of the ball could be precisely controlled. It is of interest to determine if there is evidence (with  $\alpha = 0.05$ ) to support a claim that the mean coefficient of restitution exceeds 0.82. The observations follow:

0.8411	0.8191	0.8182	0.8125	0.8750
0.8580	0.8532	0.8483	0.8276	0.7983
0.8042	0.8730	0.8282	0.8359	0.8660

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

## Extra Exercise 1

The sample mean and sample standard deviation are  $\bar{x} = 0.83725$  and  $s = 0.02456$ . The normal probability plot of the data in Fig. 9-9 supports the assumption that the coefficient of restitution is normally distributed. Since the objective of the experimenter is to demonstrate that the mean coefficient of restitution exceeds 0.82, a one-sided alternative hypothesis is appropriate.

The solution using the eight-step procedure for hypothesis testing is as follows:

1. The parameter of interest is the mean coefficient of restitution,  $\mu$ .
2.  $H_0: \mu = 0.82$
3.  $H_1: \mu > 0.82$ . We want to reject  $H_0$  if the mean coefficient of restitution exceeds 0.82.
4.  $\alpha = 0.05$
5. The test statistic is

$$t_0 = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = 2.72$$

6. Reject  $H_0$  if  $t_0 > t_{0.05,14} = 1.761$

From t table

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

## Extra Exercise 2

Bags of a certain brand of tortilla chips claim to have a net weight of 14 ounces. The net weights actually vary slightly from bag to bag and are normally distributed with mean  $\mu$ . A representative of a consumer advocacy group wishes to see if there is any evidence that the mean net weight is less than advertised. For this, the representative randomly selects 16 bags of this brand and determines the net weight of each. He finds the sample mean to be  $\bar{X}=13.82$  and the sample standard deviation to be  $s=0.24$ . Use these data to perform an appropriate test of hypothesis at 5% significance level.

# INFERENCE ON THE MEAN OF THE POPULATION, VARIANCE UNKNOWN

## Extra Exercise 3-çözüm

$H_0: \mu=170$

$H_1: \mu>170$

$\bar{X}=172.52, s=13.502, n=25$

$T_{\text{calculated}}=1.22$  (from formula)

$T_{\text{observed at } \alpha=0.05 \text{ and } df=24} = 1.7109$  (from table)

Since the calculated test statistics is not greater than 1.7109, the engineer fails to reject the null hypothesis. Thus, there is insufficient evidence to conclude that the mean hardness of iron pieces is greater than 170
